Endoscopic submucosal dissection of duodenal adenocarcinoma
arising from Brunner’s gland

Hidekazu Tanaka, Shigenaga Matsui, Hiroshi Kashida, Masatoshi Kudo

A 70-year-old man was admitted to our hospital because of a duodenal submucosal tumor (SMT) that had been detected during screening gastrointestinal endoscopy. The SMT, which was 10 mm in diameter with a small orifice at the top of the lesion, was located in the first part of the duodenum. Histopathology of a biopsy from the orifice gave a diagnosis of adenocarcinoma. Therefore, endoscopic submucosal dissection (ESD) was performed to remove the lesion en bloc (Fig. 1). Pathological examination (hematoxylin and eosin staining) of the resected specimen revealed a moderately differentiated tubular adenocarcinoma that had invaded the submucosa, but not the lymphatic vessels or vessels; tumor margins were negative (Fig. 2A,B). Immunohistochemical staining revealed that the carcinoma cells were positive for MUC6 (Fig. 2C), but negative for pepsinogen 1 (Fig. 2D). Thus, this duodenal tumor was confirmed as a duodenal carcinoma arising from Brunner’s gland.

Duodenal adenocarcinoma from Brunner’s gland is very rare and most cases are treated by surgical resection [1]. Brunner’s gland is a mucus-secreting acinar gland located in the submucosa of the duodenum. Therefore, an adenocarcinoma arising from Brunner’s gland resembles an SMT. ESD can be a good treatment selection in adenocarcinoma of duodenum from Brunner’s gland.
